Acute respiratory infections (ARI) are very common in children and often prompt parents to seek medical advice. Increased susceptibility to ARI is caused by a number of factors, including genetically determined imbalances in cytokine production. The aim of this study was to analyze the frequency of 6 clinically relevant polymorphisms of proinflammatory cytokine genes in girls predisposed to recurrent respiratory infections. The study was conducted in girls aged 7–17 years who were undergoing a routine medical checkup. A group of children with frequent respiratory infections was identified. The following polymorphisms were analyzed for possible associations with predisposition to frequent respiratory infections: *IL1β T-31C* (rs1143627), *IL1β T-511C* (rs16944), *IL1β C-3953T* (rs1143634), *IL1β G-1473C* (rs1143623); *IL6 C-174G* (rs1800795), and *TNFα G-308A* (rs1800629). For polymorphism detection, PCR and gel electrophoresis were used. The following alleles were found to be associated with an increased risk for recurrent respiratory infections in girls aged 7–17 years: C-31 (rs1143627) (OR = 2.05; CI: 1.16–3.64;  $p = 0.013$ ) and C-511 (rs16944) (OR = 3.11; CI: 1.25–7.76;  $p = 0.013$ ) of the *IL-1β* gene.

**Keywords:** recurrent respiratory infections in children, pro-inflammatory cytokines, gene polymorphism

Респираторные заболевания (ОРЗ) относят к числу наиболее распространенных заболеваний детского возраста и служат поводом частого обращения за медицинской помощью. Повышенная заболеваемость детей определяется целым рядом факторов, в том числе наличием дисбаланса в системе цитокинов, уровень синтеза которых генетически детерминирован. Целью работы было проанализировать особенности распределения шести клинически значимых полиморфных локусов в генах провоспалительных цитокинов у девочек с частыми респираторными заболеваниями. Среди девочек 7–17 лет, проходящих плановый профилактический осмотр, на основании анамнеза была выделена группа часто болеющих детей. Проведен анализ ассоциации полиморфных вариантов генов провоспалительных цитокинов *IL1β T-31C* (rs1143627), *IL1β T-511C* (rs16944), *IL1β C-3953T* (rs1143634), *IL1β G-1473C* (rs1143623) в гене интерлейкина-1β; *IL6 C-174G* (rs1800795) — в гене интерлейкина-6 и *TNFα G-308A* (rs1800629) — в гене фактора некроза опухоли альфа с предрасположенностью к частым респираторным заболеваниям. Полиморфные варианты генов выявляли методом ПЦР с электрофоретической детекцией. Показано, что с повышенным риском рецидивирующих респираторных заболеваний у девочек 7–17 лет ассоциированы аллеи C-31 (rs1143627) (ОШ = 2,05; ДИ: 1,16–3,64;  $p = 0,013$ ) и C-511 гена *IL-1β* (rs16944) (ОШ = 3,11; ДИ: 1,25–7,76;  $p = 0,013$ ).

**Ключевые слова:** часто болеющие дети, провоспалительные цитокины, полиморфизм генов

To date, it has been convincingly demonstrated that the immune system plays a critical role in disease progression. In both health and pathology, immune response is regulated by cytokines, the key mediators of cell-cell interactions in the immune system [1, 2]. An imbalance between pro- and anti-inflammatory cytokines compromises immune defense against infection and leads to chronicity [3]. The intensity of cytokine secretion depends on the expression of cytokine-encoding genes, which, in turn, is determined by the presence of persistent microorganisms and

genetic features of the host [4]. Single nucleotide polymorphisms (SNPs) of human genes coding for immunocompetent molecules determine the level of cytokine production in response to infection, affecting the clinical course of the disease [5–7]. So far, a number of polymorphic loci have been identified in promoter regions of the genes involved in the production of proinflammatory cytokines (*IL1β*, *IL6*, *TNFα*, etc.) [8–12].

Acute respiratory infections (ARI) are very common in childhood. A child falls in the “frequently ill” category if he/she

has more than 6 episodes of ARI a year; this definition refers to repeated or recurrent viral, bacterial or mixed infections of ear, nose and throat (adenoiditis, tonsillitis, otitis), upper (laryngitis) or lower respiratory tract (tracheitis, bronchitis, pneumonia) developing as a result of compromised immunity or inadequate therapy for ARI [13–15]. Increased susceptibility to ARI is determined by a few factors, including genetic ones. There is an ongoing search for possible immunogenetic markers of such predisposition.

The aim of our study was to explore possible associations between the polymorphisms of genes coding for key proinflammatory cytokines and predisposition to frequent respiratory infections in girls aged 7 to 17 years.

## METHODS

We examined 116 girls aged 7 to 17 years residing in Samara who visited a pediatric/adolescent gynecologist for a routine checkup in 2014–2016. The following inclusion criteria were applied: age between 7 and 17 years; the absence of severe organic pathology; normal physical, sexual and cognitive development. Exclusion criteria: age outside the specified range; severe organic pathology; developmental abnormalities. We analyzed the medical history of the patients (frequency of respiratory infections and their course) and allele and genotype frequencies for proinflammatory cytokine genes using PCR with gel electrophoresis (SNP-EXPRESS assay; Litech; Russia). We searched for the following SNPs: *IL1β* T-31C (rs1143627), *IL1β* T-511C (rs16944), *IL1β* C-3953T (rs1143634), *IL1β* G-1473C (rs1143623); *IL6* C-174G (rs1800795), and *TNFα* G-308A (rs1800629). DNA was isolated from the buccal mucosa using an express DNA isolation kit (Litech; Russia). SNPs selected for our study are associated with human immune status and were proposed as clinically and diagnostically relevant at the 15th International Histocompatibility and Immunogenetics Workshop in Brazil in 2008 [16].

DNA was amplified in a DTlite-4S1 thermocycler (DNA-Technology; Russia). The observed genotype frequencies were tested for conformity to Hardy-Weinberg expectations using Pearson's  $\chi^2$ . We measured possible associations and assessed the significance of differences in the distribution of categorical variables (odds ratios and 95% confidence intervals). Statistical analysis was performed online on the website of the Institute of Human Genetics (Munich, Germany) using DeFinetti software [17]. The minor alleles were hypothesized to be risk alleles and were analyzed in all combinations.

## RESULTS

The analysis of clinical data and medical histories revealed that 56.9% of the participants had ARI 6 to 10 times a year. Of them, 10.6% had a chronic ENT pathology (tonsillitis, pharyngolaryngitis) with frequent relapses (4 to 6 times a year) in the setting of acute viral and/or bacterial infection. The girls were divided into 2 groups: 65 girls constituted the group of children with recurrent respiratory infections and 51 girls made up the group without recurrent ARI.

The genotype frequency of 5 out of 6 analyzed SNPs conformed to the Hardy-Weinberg equilibrium. The only exception was *TNFα* (G-308A); therefore, this polymorphism was excluded from further analysis (see Table).

The analysis of allele/genotype frequencies of the genes encoding proinflammatory cytokines demonstrated that the general sample was dominated by the carriers of the alleles T-31, G-1473 and C-3953 in the *IL1β* gene ( $p < 0.05$ ) determining

the high levels of the encoded cytokines. In the case of *IL1β* (T-511C) and *IL6* (C-174G), the alleles associated with high and low levels of *IL1β* and *IL6* were distributed in our sample relatively equally.

Comparison of individual polymorphisms occurring at the clinically relevant loci of the studied cytokine genes and associated with high/low levels of their expression revealed that homozygous and heterozygous C alleles at positions 31 and 511 of the *IL1β* gene were significantly more frequent in the group of girls suffering from recurrent infections. The presence of the C-31 allele increased the risk of frequent respiratory infections twofold (OR = 2.05; CI: 1.16–3.64) in comparison with the T-31 allele. The highest risk of recurrent infections was detected in the carriers of the CC genotype in comparison with heterozygous CT carriers (OR = 2.58; CI: 1.14–5.85) and the pooled CT and TT genotypes (OR = 2.65; CI: 1.25–5.63). The presence of any C-511 allele variant also indicated a high risk of recurrent respiratory infections (OR = 1.68; CI: 0.99–2.83;  $p = 0.053$ ). The risk of frequent respiratory infections increased more than threefold in the carriers homozygous for CC in comparison with heterozygous CT (OR = 3.28; CI: 1.22–8.79), homozygous TT (OR = 2.9; CI: 1.03–8.17) and the pool of children with CT or TT (OR = 3.11; CI: 1.25–7/76) at -511C/T of the *IL1β* gene.

We failed to establish a statistically significant association between recurrent respiratory infections and the *IL6* (C-174G) polymorphism, but the girls suffering from recurrent infections were homozygous for the G allele associated with high levels of *IL6* 1.5 times as rare as the girls without recurrent respiratory infections (OR = 0.57; CI: 0.20–1.59;  $p = 0.77$ ).

## DISCUSSION

Long-lasting and frequent respiratory infections, especially at early age, present a medical challenge yet unsolved, creating a serious social and economic burden for the family and the society in general. The contemporary view on the problem is that the primary causes of high susceptibility to infection in children are the immaturity of the immune system and genetic predisposition [18, 19]. Cytokines play an important role in defense against pathogens: they regulate response to infection not only at the immune system level but also at the level of the whole organism. So far, extensive evidence has been accumulated suggesting that SNPs of cytokine genes can be functional and alter expression of the latter. Such functional polymorphisms hereditarily determine the levels of cytokine production in an individual, affecting the progression and outcome of infectious diseases and immunopathological processes [20]. Anti-inflammatory cytokines play a central role in the formation and regulation of inflammatory response in both innate and adaptive immunities. Therefore, research into the polymorphisms of genes coding for key proinflammatory cytokines can result in the emergence of new diagnostic and therapeutic approaches [21, 22].

In this study, we analyzed associations between polymorphisms of genes coding for key proinflammatory cytokines and predisposition to recurrent respiratory infections in 7 to 17-year old girls. Clinically relevant functional polymorphisms were assessed, including *IL1β* (T-31C), *IL1β* (T-511C), *IL1β* (C-3953T), *IL1β* (G-1473C), *IL6* (C-174G), and *TNFα* (G-308A).

In the first stage of the study, we analyzed allele/genotype frequencies of polymorphic variants of the genes encoding proinflammatory cytokines in all study participants regardless of their predisposition to frequent ARI and tested the conformity of the observed data to the Hardy-Weinberg equilibrium. This is an

**Table.** Polymorphic allele and genotype frequencies for the genes encoding proinflammatory cytokines in girls aged 7 to 17 years

**Note:** ARI — acute respiratory infections; \* — statistically significant differences in the allele frequency at the given locus ( $p < 0.05$ ); \*\* — statistically significant associations with increased risk of respiratory infections.

important stage because if observed frequencies are consistent with those predicted by the Hardy–Weinberg equation, it means that patient selection for a genetic study is adequate. The frequencies of 5 out of 6 analyzed polymorphisms was consistent with the Hardy–Weinberg equilibrium, except for *TNFα* (G-308A). For the G-308A polymorphism of the *TNFα* gene, the frequency of the heterozygous genotype observed in the general sample was different from the predicted frequency. This could be explained by the insufficient number of observations and the character of allele distribution for this locus in the studied group. Therefore, *TNFα* (G-308A) was excluded from further analysis.

The analysis of allele and genotype frequencies of *IL1β* and *IL6* revealed that the general sample was dominated by the carriers of the T-31, G-1473 and C-3953 polymorphisms of the *IL1β* gene and the G-174 polymorphism of the *IL6* genes. The distribution of *IL1β* (T-511C) alleles was relatively even. The pattern of allele/genotype distribution for this polymorphism was similar to that observed in the European female population

[23] and Russian females residing in Moscow [24], which may indicate the evolutionary advantage of the alleles that determine high levels of proinflammatory cytokines in the Caucasian population.

The subsequent analysis of the associations between predisposition to frequent ARI and the carriership of the studied alleles at the polymorphic loci of the genes encoding proinflammatory cytokines demonstrated that the presence of the C-31 and C-511 alleles in the *IL1β* gene significantly increased the risk of recurrent respiratory infections (2- to 3-fold), especially in the homozygous patients. In the girls with recurrent respiratory tract infections, the G allele in locus 174 of the *IL-6* gene was 1.5 times rarer ( $p > 0.05$ ). The discovered association between the polymorphic C-31 and C-511 alleles of the *IL1β* gene and frequent respiratory infections is consistent with the literature: *IL-1β* plays a central role in the generation and regulation of immune response against infection; carriership of polymorphic variants at positions 31T and 511T in most cases leads to an increase in the production of this cytokine *in vivo*.

and *in vitro* in comparison with C alleles, whose carriership increases the severity and frequency of respiratory infections in children and adults [25–27].

For some European populations, *IL1β* (T-31C) is in 100% linkage disequilibrium with *IL1β* (T-511C) [28], which seems to explain similar risks associated with this pair of SNPs.

The fact that only 2 SNPs of the *IL1β* gene were significantly associated with frequent respiratory infections suggests the need for identifying the subgroups with high prevalence of bacterial/viral infections, the presence/absence of allergies, etc. in the general sample of children predisposed to recurrent ARI, as well as the need for a larger patient sample. At the same time, the cytokine system is a polymorphic, highly reliable pleiotropic regulatory network of mediators whose biological effects are exerted in a cascade manner, are very diverse and sometimes excessive [29]. Therefore, a decrease in the expression of one or several cytokine genes and the resulting low production of the peptide mediator will not always be accompanied by a pronounced pathology. This means that research into the effects of polymorphisms in the cytokine genes should not be limited to the analysis of carriership of individual polymorphic variants occurring in a few cytokine genes. It is important to consider linked inheritance, mutual effects, interactions with

receptors and other factors affecting the cytokine status in health and pathology.

## CONCLUSIONS

1. The studied group of 7 to 17-year old girls residing in Samara was dominated by the carriers of the alleles T-31, G-1473, C-3953 in the *IL1β* gene and the G-174 allele in the *IL6* gene.
2. The presence of the alleles C-31 and C-511 in the *IL1β* gene was associated with the increased risk of recurrent respiratory infections.
3. The established association between the studied gene variants and respiratory infections dictates the need for further research into the functional polymorphisms of cytokine genes aiming at developing new diagnostic approaches, prevention measures and personalized therapies.
4. The analysis of carriership of individual polymorphic gene variants in the cytokine system is not enough for the comprehensive assessment of individual immunogenetic features and the search for genetic markers for prediction, prevention and personalized treatment; it is important to account for linked inheritance, mutual effects, interactions with receptors and other factors affecting the cytokine status in health and pathology.
